

Build muscle. Lean up. One plan, not two.

A recomposition plan built around food you already eat — steak, mince, eggs, rice, potato — sized correctly and scaled up gradually to where it needs to be.

98kg

CURRENT WEIGHT

15%

BODY FAT

2,950

TARGET KCAL/DAY

1 The goal & the approach

The goal is a true recomposition: build muscle *and* bring body fat down at the same time — not one after the other. At 98kg and 15% body fat, you're already lean enough that this works best from maintenance-to-slight-surplus calories, not a deficit. Right now you're eating ~2,300–2,500 kcal/day, sometimes less — that's under-fueling for your size and training, and it's working against the muscle you're trying to build, not for it. The fix isn't restriction, it's getting enough food in consistently — built from four foods you already eat without issue: steak, mince, eggs, and protein shakes, plus rice and potato for carbs.

2 Starting numbers

These are a starting point, not a fixed rule — section 8 covers exactly how and when to adjust them.

CALORIES	PROTEIN	FAT	CARBS
2,950	244g	136g	188g

Protein is the priority number on this page — at ~2.5g/kg, it's what builds and protects muscle while body fat comes down. This is the final target; section 7 covers how you ramp up to it without wrecking adherence in week one.

3 Your day, meal by meal

Four meals, same structure every day — simple on purpose, so it's easy to actually hit.

Breakfast 4 whole eggs + ½ avocado + protein shake

~50g protein, ~530 kcal. Sets up the day without needing carbs this early.

Lunch Steak (250g) cooked in olive oil + rice (350g)

~82g protein, ~98g carbs, ~1,050 kcal. Main training-fuel meal of the day.

Dinner Beef mince (250g) cooked in olive oil + potato (450g)

~74g protein, ~90g carbs, ~1,135 kcal. Biggest meal — replenishes what the day's training used.

Snack 2 whole eggs + protein shake

~38g protein, ~265 kcal. Closes the protein target out, easy to fit in wherever it works.

4 Eyeballing it — no scale required

THE HAND-PORTION METHOD

Use your own hand instead of a scale. It's not lab-accurate, but it's accurate enough to hit these targets consistently — and consistent beats perfect. Sizes below are for cooked/prepared food.

2 palms

Steak or mince

Thickness and size of your palm, fingers excluded — that's your 250g protein portion at lunch and dinner.

2–3 cupped hands

Rice or potato

One cupped hand $\approx$ 130–150g cooked. Rice at lunch runs $\sim$ 2.5 cupped hands, potato at dinner $\sim$ 3.

1–2 thumbs

Olive oil

Thumb tip to first knuckle $\approx$ 1 tbsp. Use one per pan when cooking the steak and the mince.

Half a fist

Avocado

Roughly half an avocado at breakfast.

Count them

Eggs

No estimating needed — 4 in the morning, 2 at the snack.

If progress stalls for 2–3 weeks straight and you can't tell why, that's the one time to weigh food for a few days to find out where the drift actually is — not a daily requirement.

5 Budget staples

Everything here is built from six ingredients — nothing exotic, nothing that needs a special shop:

- ✓ Steak (sirloin or similar lean cut)
- ✓ Beef mince (85/15)
- ✓ Eggs
- ✓ Protein powder
- ✓ Rice & potatoes
- ✓ Olive oil & avocado

6 The flexible-meal fix

PASTA SWAP, NOT A CHEAT MEAL

When rice or potato gets repetitive, swap in pasta at roughly the same cooked weight (300g pasta $\approx$ 350g rice for carbs) — same targets, less monotony. If a takeout meal happens, hit protein through eggs/shake as normal earlier in the day and let takeout cover the rest. Planned flexibility is sustainable; total rigidity usually isn't.

7 Building up, not jumping in

Going from ~2,300–2,500 kcal straight to 2,950 overnight is a 20%+ jump — you'll feel overly full, adherence will drop, and you'll likely bail back to old habits within a week. Step it up instead:

- ✓ **Week 1 — ~2,600 kcal:** add the snack (2 eggs + shake) to your current eating.
- ✓ **Week 2 — ~2,800 kcal:** bring the rice and potato portions up to full size.
- ✓ **Week 3 onward — ~2,950 kcal:** full plan, olive oil and avocado included.

This isn't just about comfort — consistently under-eating relative to training load is the mechanism behind Relative Energy Deficiency in Sport (RED-S), the IOC's consensus term for chronic low energy availability. It blunts recovery and hormonal function, which directly works against building muscle. The ramp-up gets you to an adequate intake without your gut vetoing the plan in week one.

8 Timeline & how to adjust

Recomposition is slower than a pure bulk or pure cut — it's asking the body to do two things at once. Set expectations at **12–16+ weeks**, not a fast transformation.

MONITORING

Weigh in 3x/week (same conditions), track the weekly average. Waist measurement every 2 weeks. Photos every 2–4 weeks.

Reassess every 2–3 weeks: if weight/waist aren't trending and lifts are climbing, this is working — hold. If waist keeps rising with no strength gains, trim 150–200 kcal from carbs first. If strength starts dropping or you're losing weight fast, add calories back — that's muscle loss, not fat loss, and it undoes the whole point of this plan.

9 Your program

Nutrition sets the ceiling — the training program is what actually builds the muscle and shapes the recomposition. Two options, pick the one that fits where you want to focus first:

RECOMMENDED

Strong & Lean

Built specifically for strength and shape together — the direct match for "build muscle and lean up" as one combined goal, rather than choosing between the two.

share.newie.app/offerings/0FD08F08...

ALTERNATIVE

Mass 2.0

If you'd rather prioritize size first and address leanness in a second phase, this is the dedicated hypertrophy block to build off.
